# Chapter 3: Research Methodology

### 3.1 Introduction

In chapter-3, it explores the research methodology employed and is divided into three main parts: Research design, problem formulation and datasets, all components considered highly important to a study's outcome. Research design describes the overall concept and its elements employed to realize the research goals and objectives. The detailed information about the employed methods and techniques, as well as, the justification of the choice of certain sentiment analysis algorithms and machine learning models is provided. This section also looks at the procedures followed in gathering data as well as in tabulating and analyzing information so that the research is conducted systematically and scientifically. Formulating the problem can be described as the process of identifying and defining the research problem. t contains the methodology description of research questions and hypothesis, objectives in order to provide the basis for further detailed examination of the connection between news sentiment and stock price fluctuations. Databases give a comprehensive description of the data sources that were used in the research work. This entails providing a comprehensive account of the main data source as are the credible online news portals in Malaysia that include New Straits times, Bursa Malaysia and the Edge Market among others. It also provides information about the data collection process and focuses on the criteria for selection of the articles, and on the techniques used for the classification of sentiments on the granular level. The datasets section increases the degree of transparency while using the given data and highlights the reliable sources used for analysis.

## 3.2 Research Design

The study will use both quantitative and qualitative methods in the analysis of the given research questions, which are essential in examining the influence of sentiment expressed and found in financials news headlines on stock prices in the Malaysian market. Research framework for this proposal as shown in Figure 3.1.

In phase one there is problem formulation and the identification of the background to the study through literature review. In Phase 2, the researchers will gather all relevant data such as news articles retrieved from appropriate online sources concerning the Malaysian market, headlines of the articles, and the historical stock price data. Phase 3 will be involved in the main analysis processes where the extracted news headlines will be subjected to sentiment analysis both using lexicon-based and machine learning based sentiment analysis to obtain sentiment scores. This sentiment data will then be combined with the stock price data of the specific firm in question. In Phase 4, the features from the integrated dataset will be utilized to build models that are regression based and deep learning based such as LSTM and GRU to forecast the movement of the stock prices. Finally, in Phase 5 the results coming from the two phases of the sentiment analysis and stock price modelling phases will be analysed and discussed emphasising on the comparison of the most effective approaches to the sentiment analysis, revised list of relevant sentiment related features, and concluding remarks as to the practical implications of the results for multiple stakeholders. The results of the conducted research will be described and exemplified utilizing multiple forms of visualization and reporting tools for better information sharing with regard to the outcomes of the study.

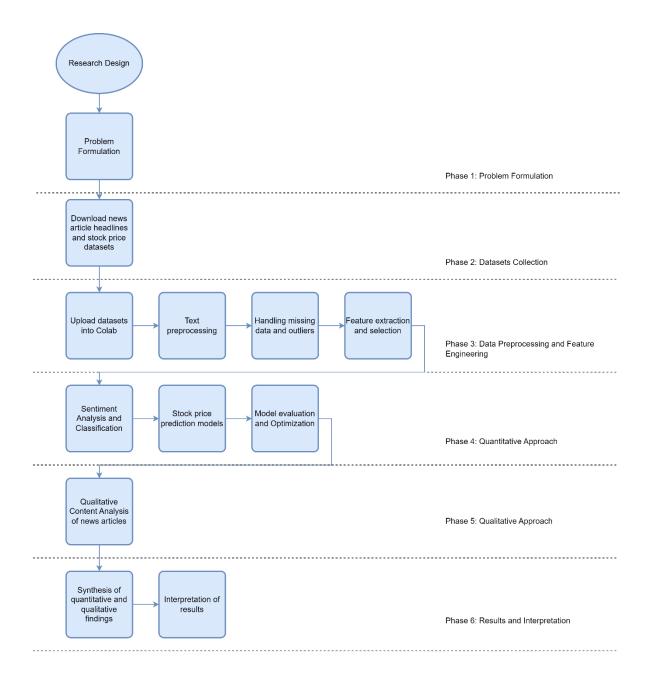

Figure 3.1: Research Framework of Proposal

## 3.3 Problem Formulation

Specific problems that the study aims to address are highlighted in Table 3.3.

### 3.4 Datasets

In sum, it is evident that the methodology of any stock price prediction model is highly dependent on the data used for testing and training the model. In the process of implementing this concept, the data accumulation phase entails the acquisition of information pertinent to the current project's analysis and modeling components. The description of practical datasets is shown in the following Table 3.5.

Dataset	Description	Data source
Textual Data	Full text of the news articles	News websites such as
		Malaysiakini, The New York
		Times, The Washington Post,
		BBC, CNN provide APIs or
		make their article content
		available for download.
		Financial Reports and Press
		Releases.
Sentiment	Numerical score representing the	Sentiment scores could be
Analysis	sentiment of the article content, typically	generated using machine
Scores	derived from a machine learning model,	learning models trained on
	Sentiment score calculated using a	labeled datasets, Lexicon
	lexicon-based approach	sentiment scores might come
		from predefined sentiment
		lexicons such as AFINN,
		VADER (Valence Aware
		Dictionary and Sentiment
		Reasoner), or the NRC
		Emotion Lexicon, which assign
		sentiment values to words and
		phrases.
		Commercial and open-source
		sentiment analysis tools and
		APIs, such as those provided by
		Google Cloud Natural

		Language API, IBM Watson, or
		Python libraries like TextBlob
		and NLTK, could also be used
		to derive these scores
Metadata	Names of the authors of the articles, dates	Web Scraping or news
	and times when the articles were	aggregators
	published.	

Table 3.2: Datasets

#### 3.4.1 News Article Data

The primary data for this research shall be the headlines that relate to financial news in Malaysia, which may be obtained from the following Malaysians reputable online newspapers; Malaysiakini, New Straits Times, Bursa Malaysia, and The Edge Market. The following news sources were identified and chosen from the list of those most prominent and credible in the Malaysian financial sphere: The news headlines will be accumulated for half a decade: From January 2018 to June 2024, so as to have a standard and sufficient amount of material to make an analysis. Such period was selected to test how different economic and market events can affect the correlation between the news sentiment and stock price fluctuation.

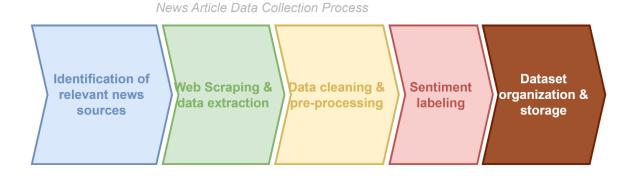

Figure 3.2: News article data collection process

	Process steps	Description
--	---------------	-------------

Relevant news sources	The trustable Malaysian online news websites that regularly cover
identification	financial and stock market news will be identified. The sources
	will be chosen depending on their standing, audience, and
	emphasis on the Malaysian financial market.
Web scraping & data	Automated web scraping techniques will be used to extract
extraction	financial news headlines from chosen online news portals. This
	procedure will require creating scripts or using web scraping tools
	to gather headlines and related metadata (such as publication date
	and article URL) systematically over 5 years timeframe.
Data cleaning &	The news headlines that have been gathered will be subjected to
preprocessing	a thorough data cleaning and preprocessing step. This will involve
	actions like eliminating duplicate entries, addressing missing
	data, and standardizing the format and structure of the headlines
	to ensure consistency across the dataset.
Sentiment labeling	Each news headline will be manually reviewed and categorize
	each news headline based on its sentiment (positive, negative, or
	neutral). This manual labeling process will act as the foundation
	for the following sentiment analysis and model training.
Dataset organization &	The cleaned and labeled news headline dataset will be organized
storage	and stored in a structured format, such as a CSV file or a relational
	database, making it easier to manage and analyze the data
	effectively.

Table 3.3: Data collection process steps

Web scrapping step	Description
1. Define the URL	Articles were scraped from the news section of the Malaysiakini
Range	website, specifically targeting URLs within a specified range. The
	range covered articles from

	https://www.malaysiakini.com/news/405000 to
	https://www.malaysiakini.com/news/710000.
2. URL Construction	A loop was set up to iterate through each URL in the defined
and Looping	range. For each URL, the newspaper3k library was used to
	download and parse the article.
3. Extraction of Data	The following information was extracted from each article:
	- Title: The news articles' headline.
	- Author: Name of author of the article.
	- Published Date: The date on which the article was published.
	- Content: The main body of text of the article.
4. Filtering Criteria	Articles were filtered based on their publication dates to include
	only those published between 2018 and 2024. This ensures that
	the analysis focuses on recent and relevant articles for past 6
	years.
5. Error Handling and	Log will skip any URLs that failed to return a valid response and
Data Storage	extracted data was stored in a panda DataFrame and subsequently
	saved to a CSV file with UTF-8 encoding to handle text data,
	including Chinese characters, accurately.

Table 3.4: Web scrapping steps

### 3.4.2 Stock Price Data

In the same regard, historical data concern to the index of stock price of the Malaysian stock market also will form part of the result headline. This data will be extracted from the Yfinance which includes mandatory columns namely Date, Open, High, Low, Close, Volume, and Adjusted Close prices. From reliable sources like the Bursa Malaysia, which is the Malaysian stock exchange or even from sources like yahoo finance or bloomberg. The following key stock market data will be collected:

- 1. Stock Prices, as shown in Table 3.8.
- 2. Trading Volume: The number of shares traded for a particular stock on a given day.
- 3. Stock Indices: Relative stock market indexes, for instance, the FTSE Bursa Malaysia KLCI often abbreviated as FBMKLCI, is the main stock market index in Malaysia.

Related stock price data of the particular stock will also be extracted for the same time period as the news article data so that both could be integrated for analysis. The data of the stock prices will be again cleaned and preprocessed so as to handle any missing data, any outliers, or else. Through the inclusion of the Malaysian stock price data, the research will be able to analyse the relationship that exists between news sentiment and actual stock price in the Malaysian market. This will be helpful to investors, traders and especially the financial analyst in a way that they will be able to comprehend the relationship between news sentiment and stock return.

Attribute	Meaning
Date	the trading date.
Open	the stock's opening price on the given date.
High	the highest price of the stock on the given date.
Low	the lowest price of the stock on the given date.
Close	the closing price of the stock on the given date.
Volume	the number of shares traded on the given date.
Adjusted Close prices	the stock's closing price adjusted for corporate actions.

Table 3.5: Attribute and meaning

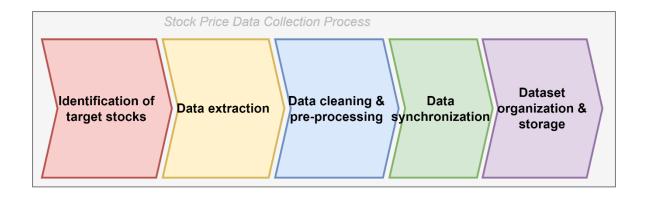

Figure 3.3: Stock price data collection process

## 3.5 Data Preprocessing and Feature Engineering

In the news article collection from the different online source, the data will go through a rigorous process of preprocessing to increase its quality for the sentiment analysis and the

stock price prediction modeling to be done on it. In feature engineering, the preprocessed news article data is formatted to a set of useful features that can be used for the analysis of sentiments and stock prices. The feature engineering step will make the dataset ready for the steps that follow sentiment analysis and stock price prediction modeling using both text data and data from the financial market to map the sentiment of news with the volatility of stock prices. Data Preprocessing steps and Feature Engineering as shown in Table 3.6 and Table 3.7, respectively.

Data Preprocessing Steps	Description
Text Cleaning	As for the data preprocessing of the news article content, they
	will be preprocessed by stripping off HTML tags, eliminating
	other characters that include, but are not limited to '&', '@',
	'£', '\$', ',', '.', '?', '/', '(', ')', '[', ']', '{', '}', ':', ';', '+', '=',
	This will assist in normalizing the text and pay more attention
	on the useful information.
Standardization	The text will be then transformed into a simpler lower case
	letters type because such variations as upper and lower cases
	are distinguished by the computer system.
Tokenization	The text of the news article will be preprocessed by dividing
	the text into individual words or tokens, which is going to be
	an important stage in the natural language processing
	procedures.
Stopword Removal	Special specific inflexional words that have low semantic
	importance for texts, including "the," "a," and "and," will be
	eliminated from the text to highlight important terms.
Lemmatization/Stemming	Lemmatization or stemming of the words will take place
	where all the words will be converted to their base or root
	form. This contributes to building the consistency and
	decreasing the number of features to reduce the dimensionality
	of text data.

Table 3.6: Data Preprocessing steps

Feature Engineering	Description
key steps	
Sentiment Score	The sentiment of each news article headline will be determined as
Calculation	positive, negative, or neutral depending on the scores derived from
	both the lexicon-based methods and machine learning sentiment
	analysis methods. The sentiment scores to be obtained will
	incorporated in the modeling process to come up with the features.
Textual Feature	Additional textual features will be extracted from the news article
Extraction	headlines, such as:
	• Term Frequency-Inverse Document Frequency (TF-IDF):
	Estimating the position of words in an article in regard to the
	significance degree of the words versus the total number of articles.
	• N-grams: Splitting the text into n-grams, which are two
	(bigrams), three (trigrams), four or more consecutive words
	to combine contextual data, and frequently appearing terms.
	<ul> <li>Named Entity Recognition: Selecting and extracting proper</li> </ul>
	nouns like the names of the companies from the headlines.
Temporal Feature	To capture the temporal dynamics of news sentiment and its impact
Engineering	on stock prices, the following features will be created:
	Publication Date and Time: Adding the information on when
	the article was published and then use temporal data analysis.
	Lagged Sentiment Scores: Including leads for the sentiment
	scores such as sentiment score of the previous day or the
	previous week due to time lags of sentiments on stock prices.
Categorical Feature	Non numerical variables like the source of articles for example from
Engineering	New Straits Times, Bursa Malaysia, The Edge Market as well as the
	author of the articles will be coded to help in debiasing the data
	collected.
Stock Market	Other features of the stock market which will be incorporated into
Feature Integration	the set of predictors for the stock price prediction models include
	historical stock prices, trading volumes, and market indices.
	Table 3.7: Feature Engineering key steps

Table 3.7: Feature Engineering key steps

# 3.6 Quantitative Approach

The quantitative component of the research design will involve the following key elements illustrated in Table 3.8.

Quantitative	Description
component	
Data Collection	<ul> <li>The main sources of data will be collected from trusted online news portals in Malaysia, such as the New Straits Times, Bursa Malaysia, and The Edge Market.</li> <li>Financial news or article headlines will be collected for a period of 5 years to create a complete dataset for analysis.</li> <li>Historical data on stock prices for the same period will be sourced from reputable sources such as Bursa Malaysia.</li> </ul>
Sentiment Analysis	<ul> <li>Classification of sentiment will be conducted on a sentence-by-sentence basis, identifying whether each sentence in the news headlines is positive, negative, or neutral.</li> <li>Traditional sentiment analysis methods like Naive Bayes and Lexicon-based approaches will be used alongside more sophisticated machine learning models like Long Short-Term Memory (LSTM) networks for sentiment analysis.</li> <li>The effectiveness of these sentiment analysis strategies will be assessed and compared to identify the most effective methods for predicting stock price movements in the Malaysian market.</li> </ul>
Stock Price Prediction Models	<ul> <li>The relationship between the sentiment expressed (positive, neutral, negative) in news headlines and historical stock prices will be analyzed to uncover patterns and temporal dependencies.</li> <li>Traditional forecasting models, such as ARIMA, will be employed as a baseline for comparison.</li> <li>Advanced predictive models, including LSTM and Gated Recurrent Unit (GRU) networks, will be developed and</li> </ul>

- optimized to improve the precision when forecast stock price based on news sentiment.

   The performance of these models will be evaluated using
  - The performance of these models will be evaluated using metrics such as root mean squared error (RMSE) and mean absolute error (MAE).

Table 3.8: Quantitative component

### 3.6.1 Lexicon-based Approach

To aid the sentiment analysis aspect of the research, sentiment lexicons will be used. These lexicons are collections of words and their corresponding sentiment ratings. These dictionaries will act as a basis for the conventional algorithms used in sentiment analysis, such as the Lexicon-based method. The study will investigate the effectiveness of different sentiment lexicons, such as general-purpose and finance-specific lexicons, to identify the most suitable resources for the Malaysian financial context.

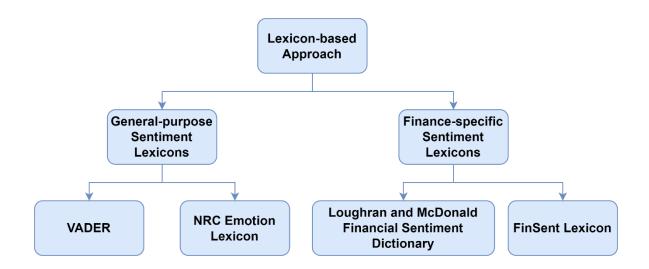

Figure 3.4: Lexicon-based approach

Lexicon-based approach		Description
	VADER (Valence	VADER is a sentiment analysis tool that focuses
	Aware Dictionary	on emotions conveyed in social media, using

General-purpose	and Sentiment	lexicons and rules. It offers an extensive
Sentiment	Reasoner)	compilation of words along with their
Lexicons		corresponding sentiment scores.
	NRC Emotion	The NRC Emotion Lexicon is a popular sentiment
	Lexicon	lexicon that links words with eight fundamental
		emotions (anger, surprise, anticipation, fear, trust,
		sadness, disgust, and joy) and two sentiment
		polarities (positive and negative).
Finance-specific	Loughran and	This specialized dictionary was created for the
Sentiment	McDonald	financial domain and includes a comprehensive
Lexicons	Financial	list of words with their corresponding sentiment
	Sentiment	ratings in the context of financial reporting and
	Dictionary	news.
	FinSent Lexicon	The FinSent Lexicon is a sentiment lexicon
		specifically designed for analyzing sentiment in
		the financial domain, using financial text data for
		its creation and validation.

Table 3.9: Lexicon-based approach and its description

Sentiment Lexicon
Selection

Text
Preprocessing

Sentiment
Scoring

Sentiment
Classification

Evaluation

Figure 3.5: Lexicon-Based Approach steps

Lexicon-based	Description
sentiment analysis	
steps	

1.Sentiment	Several sentiment lexicons will be evaluated, such as the VADER	
Lexicon Selection	(Valence Aware Dictionary and Sentiment Reasoner) lexicon. It	
	specifically designed for social media text, and the NRC Emotion	
	Lexicon, which provides associations between words and eight basic	
	emotions.	
2.Data Pre-	The news article content will undergo standard text preprocessing steps,	
processing	including:	
	1. Cleaning text– Remove unnecessary content like HTML tags, special	
	characters, punctuations, and digits from text.	
	2. Standardization in lower case – Standardize text in the same lower	
	case as the computer differentiates between lower case and upper case.	
	3. Tokenization – Convert sentences into words.	
	4. Stopword removal – Words that provide no meaningful information	
	such as 'this', 'a', 'there', and 'an'.	
	5. Lemmatization or stemming - to simplify words by stripping off	
	affixes and returning them to their base form.	
3.Sentiment	For each news article, the sentiment score will be calculated by the sum	
Scoring	of sentiment scores of the individual words in the text, based on their	
	association with positive or negative sentiment in the selected	
	lexicon(s). For example, sum of sentiment of 1 is positive, while 0 is	
	negative.	
4.Sentiment	The news articles will be classified into positive, neutral, or negative	
Classification	sentiment categories based on the calculated sentiment scores. This can	
	be done by setting appropriate thresholds or using a rule-based	
	approach.	
5.Evaluation	The performance of the lexicon-based sentiment analysis will be	
	evaluated using appropriate metrics, such as precision, recall, accuracy,	
	and F1-score. This is able to provide insights into the effectiveness of	
	the chosen lexicons and the overall reliability of the sentiment	
	classification.	
T 11 2 10	Lavison based sentiment analysis stone (Snivestove et al. 2022)	

Table 3.10: Lexicon-based sentiment analysis steps (Srivastava et al., 2022)

### 3.6.2 Machine Learning Models

Training of a model in sentiment analysis in machine learning involves the use of a training dataset which has labels, and categorizing of a text or a document in terms of positive, negative or neutral sentiment. It is often easier and more accurate than the aforementioned lexicon-based approach because it can learn such patterns and relationships from the data. But, it needs a bigger and more marked up data corpus for training and may be slower.

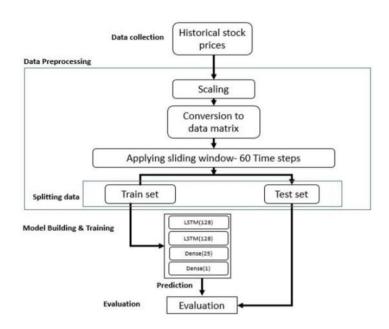

Figure 3.6: Machine learning-based sentiment analysis framework (Gangthade, 2024)

Process	Description		
1.Development	Collection of data in .csv text file.

## 3.6.3 Sentiment Classification Refinement (Hybrid Approach)

The mixed strategy based on the usage of both the lexicon-selected benchmark and machine learning tools to take advantage of both approaches. In this case, the lexicon-based method is first applied to give a raw sentiment score that is then further adjusted by a machine learning model trained with sentiment labelled data. This can help in giving more accurate and refine sentiment analysis especially when dealing with more elaborate or vague text.

Sentiment Classification Refinement by hybrid approach

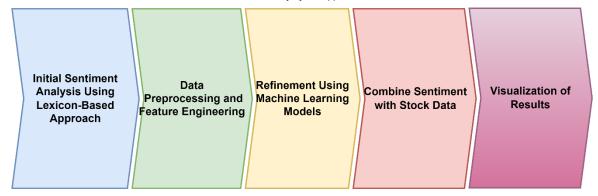

Figure 3.8: Sentiment classification refinement by hybrid approach

## 3.6.4 Deep Learning Techniques

As was mentioned before, the modern advancements in deep learning have contributed to the improvement of the sentiment analysis approaches. Some of these are the application of feed forward neural networks for instance convolutional neural networks (CNNs) and recurrent neural networks (RNNs) used in prevailing semantic and contextual nuances of the text data. Analyzing the results of the current deep learning models, a higher level of accuracy compared to traditional machine learning can be achieved, especially in tasks that require an understanding of the depth of the language and sentiment.

Among them, the necessity of the labelled data, the complexity of sentiment patterns identified in the text and the availability of computational power are to be taken into consideration.

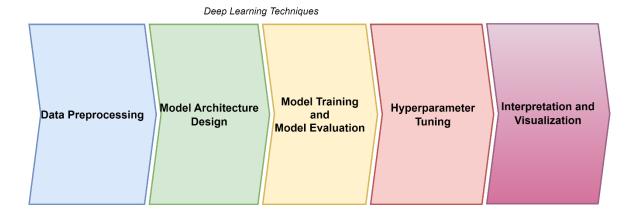

Figure 3.9: Deep Learning Techniques

## 3.7 Qualitative Approach

The qualitative components of the research design are described in Table 3.11.

Qualitative	Description
component	
Interviews with Financial Experts	<ul> <li>Conducted semi-structured interviews with financial analysts, traders, and investment professionals to gain insights based on their perspectives on the role of sentiment analysis in stock price forecasting and decision-making.</li> <li>The interviews will explore the practical challenges, limitations, and potential applications of sentiment analysis in the Malaysian stock market.</li> </ul>
Content Analysis of News Articles	<ul> <li>In addition to the quantitative sentiment analysis of news headlines, a qualitative content analysis of the full text of selected news articles will be performed.</li> <li>This analysis will provide a deeper understanding of the contextual factors and nuances that may impact the relationship between the movements of stock price with news sentiment.</li> </ul>

Table 3.11: Qualitative component

# 3.8 Results and Interpretation

In this phase, the major findings from sentiment analysis and the chosen stock price prediction models elaborated in the previous phase. The results and their interpretation will be structured as follows:

Type of Results	Description
Sentiment	Starting with the Lexicon-based methods, the performance of the various
Analysis	sentiment analysis techniques will also include machine learning-based
Findings	methods for comparison. This will include:
	• Presenting the accuracy, precision, recall, and F1-score that was
	obtained by each of the sentiment analysis techniques in
	categorizing the news headlines to positive, negative, and
	neutrality.
	Considering the advantages and disadvantages of the various
	methods for the sentiment analysis comparing the Malaysian
	stock exchange to international markets.
	• Determining the type of sentiment analysis technique, or a
	combination thereof, that would be most suitable for the problem
	domain in question and the particular data set.
	• Discussing if any features, such as trends in the sentimental scores
	of the news articles over time, or entertained news sources could
	be observed.
Stock Price	Stock price prediction models, that include the news sentiment features,
Prediction	shall be analyzed and their performance assessed and discussed. This will
Modeling	include:
Results	Presenting the overall metrics measurement indicators, including
	RMSE, MAE, and R-squared with respect to memory-based,
	traditional regression analysis, and deep learning methods,
	including LSTM and GRU.
	• Evaluating the performance of the models that incorporate
	sentiment features against the models that only depend on the
	target stock's historical prices.
	Assessing the effectiveness of the proposed classification      anguage having the feeture importance to identify that of the
	approach using the feature importance to identify that of the
	sentiment-related features and define which of them significantly
	affect the stock price (i. e., certain words, sentiment score, etc.).

	D 111	
	• Recalling any prominent findings or trends that can be identified	
	from the model results together with the relative relevance of	
	positive, negative, and neutral sentiments impacting on stock	
	prices.	
Practical	A comprehensive interpretation of the findings will be provided and	
Implications	discuss their practical implications for different stakeholders, including:	
	• Investors and traders: Knowledge about various aspects that has	
	to do with integrating news sentiment analysis in equity	
	investment as a means of improving stock trading.	
	• Financial analysts: Suggestions on how they could enhance their	
	utilization of sentiment analysis approaches to enhance their	
	predictions of stock rates and other forms of market research.	
	<ul> <li>Policymakers and regulators: Information on how news</li> </ul>	
	sentiments work in the context of the stock market which would	
	help decision makers crack the whip for formulating policies and	
	implementing regulations in the stock market.	
Limitations and	The conclusion of the study and suggest possible improvement and	
Future Research		
Directions	further research recommendation relevant to the conduct of the research	
Directions	study. This may include:	
	Analyzing the generalization of the discoveries, especially in the	
	context of transferring the obtained results to other sectors or	
	industries in the Malaysian stock exchange.	
	Finding potential places for suggestion like possible new	
	approaches to the sentiment analysis, new sources of data, or	
	analyzing how specific news affect the stock prices.	
	• In terms of future research, based on the current study, specific	
	research topics one might consider proposing for investigation by	
	other scholars include the improvement of the current and still	
	rather simple methods of the predictive model, the investigation	
	of investor sentiment, or the cross-market analysis of the news	
	sentiment.	
Visualization	With regards to the presentation of the research results and the insights	
and Reporting	acquired by the study, the following visualization and reporting aspects	

will be incorporated into the research study: These will assist in improving the presentation and analysis of the outcomes of the study.

- 1. For Sentiment Analysis Finding, it can be visualized as follows:
  - Sentiment Score Distribution: These headlines will be grouped under positive, negative and the neutral category and a pie chart or bar graph utilized in depicting the findings.
  - Sentiment Trends over Time: To show the temporal changes on the sentiment scores, line charts commonly known as area plots will be used and where there is significant fluctuation, the specific periods will be noted.
  - Sentiment by News Source: To compare the sentiment scores different news sources a bar graphs or heat maps would be used to determine if there are any bias or variation in reporting.
- 2. For Stock Price Prediction Modeling, it can be visualized as follows:
  - Model Performance Metrics: The main evaluation measures, including RMSE, MAE, and R-squared, of the method and all the compared models (e.g., LSTM, GRU, and conventional regression models) will be illustrated in tabular and line chart forms.
  - Actual vs. Predicted Stock Prices: Thus, line charts or scatter plots
    will be used to display the actual stock prices and the model's
    forecasted values to evaluate the models' calibration and fitness.
  - Feature Importance: Feature importance plots or bar charts will be used to display the contribution of the sentiment-related features and other stock market factors to the model's decision-making process.
- 3. For overall reporting, it can be visualized as follows:
  - Executive Summary: Summary of the most important fact, the relevance of the findings and, of course, the contribution to the academic literature.
  - Detailed Results and Interpretations: The elaborate explanation and discussion on the assessment of sentiment analysis and stock price modeling as described in the earlier sections of this paper.

- Practical Recommendations: Guidelines and suggestions for different users including shareholders, analysts covering the firm and policy makers.
- Limitations and Future Research: An evaluation of the study's restrictions and future recommendations about how the current work can be expanded upon by the next researcher.
